**STATUS CONFIRMATION FOR THESIS
DOCTOR OF PHILOSOPHY**

**AN INTRUSION DETECTION SYSTEM FOR DDOS FLOODING ATTACKS
ON IPV6 NETWORKS USING DEEP LEARNING TECHNIQUES**

ACADEMIC SESSION: 2020/2021

I, **AHMED ALEESA**, agree to allow this Thesis to be kept at the Library under the following terms:

1. This Thesis is the property of the Universiti Tun Hussein Onn Malaysia.
2. The library has the right to make copies for educational purposes only.
3. The library is allowed to make copies of this Thesis for educational exchange between higher educational institutions.
4. The library is allowed to make available full text access of the digital copy via the internet by Universiti Tun Hussein Onn Malaysia in downloadable format provided that the Thesis is not subject to an embargo. Should an embargo be in place, the digital copy will only be made available as set out above once the embargo has expired.
5. ** Please Mark (√)

PERPUSTAKAAN TUNKU TUN AMINAH

This thesis is dedicated:

- To the sake of Allah, my Creator, and my Master, my great teacher and messenger, Prophet Muhammed (may the peace and blessings of Allah be upon him, his family, his Companions and all those who follow him exactly till the Day of Judgement), who taught us the purpose of life.
- To my great parents, who never stop giving of themselves in countless ways.
- To my beloved brother and sisters; particularly my dearest brother, Radwan, who stands by me when things look bleak.
- To my love, soulmate and wife who has been a constant source of love, support and encouragement. I am truly thankful for having you in my life
- To my supervisors who were with me during my PhD journey
- To all my family, the symbol of love and giving.
- To my friends who encourage and support me.
- To all the people in my life who touch my heart.

I dedicate this research.

PTAAUTHM
PERPUSTAKAAN TUNKU TUN AMINAH

ACKNOWLEDGEMENT

First and foremost, I must acknowledge my limitless thanks to Allah, the Ever-Magnificent; the Ever-Thankful, for His help and bless. I am sure that this work would have never become truth, without His guidance.

I also would like to express my wholehearted thanks to my family for the generous support they provided me throughout my entire life and particularly through the process of pursuing the master's and PhD's degree. Because of their unconditional love and prayers, I have the chance to complete this thesis. I owe a deep debt of gratitude to my parents for allowing me to study and support me emotionally and financially since the first day I came to Malaysia. I always knew that they believed in me and wanted the best for me. I would like to express my sincere appreciation to my main supervisor Dr Nan Bin Mad Sahar and my co-supervisors Dr Bilal Bahaa Zaidan and Associate Professor Dr Aws Alaa Zaidan for his thoughtful insights, helpful suggestions and continued support in the form of knowledge, enthusiasm, and guidance throughout the duration for this research. towards the compilation of this thesis. they showed me what it means to be dedicated, each in his unique way particularly to my best supervisors ever, who were teachers, leaders, brothers, and friends. who were always advised, motivate, and support me during all phases of my research.

I would like to take this opportunity to say warm thanks to all my beloved friends, who have been so supportive along the way of doing my thesis. Also, my deepest thanks go to all people who took part in making this thesis real. Finally, I would like to express my gratitude and appreciation to the Malaysian Government and Universiti Tun Hussein Onn Malaysia for the facilities and support. Thank you

ABSTRACT

The news about distributed denial of service (DDoS) attacks is rapidly increased around the world. Many services of companies and/or governments are victims of the attack. The main purpose of DDoS attacks is to overload the service for a long time, rather than to steal money or data from the targets. Since the user might not re-use services jammed by crackers, a company attacked by the crackers will lose many benefits.

Major challenges are faced by the researchers are the unavailability of the dataset such as “no labelled DDoS attacks for IPv6, no data available online for download or use, few datasets on the internet but the security institutes or researchers who own it are kept private even for the research purposes”. In this research, I developed a DDoS-IPv6 dataset from real attacks traffic that contains 96 extracted features, the generated IPv6-DDoS dataset where had been collected by capturing attacks packets can be converted into network flows that contain rich metadata about the statistics of each flow, which are composed of the captured packet data. These flows are structured in the form of tabular data and contain both continuous and categorical features. Then deployed deep learning technique as intrusion detection system on the developed dataset, moreover optimised deep learning hyperparameters (i.e. the number of hidden layers/neurons, etc.) in order to find the optimal deep learning model, and check if the optimisation of layers/neurons would contribute to improving the accuracy.

Accordingly, the result of the optimal deep learning technique for the four models with the developed dataset DDoS-IPv6 are between 99.79% and 99.996% and losses are between 0.0014% and 0.781%. I found that all the techniques succeeded to classify/detect IPv6 attacks and this will lead to new further research that needs to be developed in this area.

ABSTRAK

Berita mengenai serangan Penafian Perkhidmatan (DDoS) telah pesat meningkat di seluruh dunia. Banyak perkhidmatan Syarikat dan/atau kerajaan adalah mangsa serangan. Tujuan utama serangan DDoS adalah untuk sarat Perkhidmatan untuk masa yang lama, dan bukannya untuk mencuri wang atau data dari target. Oleh kerana pengguna mungkin tidak menggunakan semula perkhidmatan yang sesak oleh keropok, sebuah syarikat yang diserang oleh keropok akan kehilangan banyak faedah.

Cabaran utama yang dihadapi oleh penyelidik untuk membangunkan penyelidikan itu sendiri dan ketiadaan Dataset seperti "Tiada serangan DDoS yang dilabelkan untuk IPv6, tiada data yang ada dalam talian untuk muat turun atau penggunaan, beberapa set data di internet tetapi institusi keselamatan atau penyelidik yang memiliki ia disimpan swasta walaupun untuk tujuan penyelidikan. Dalam kajian ini, kami membangunkan DDoS-IPv6 Dataset daripada lalu lintas serangan sebenar yang mengandungi 96 ciri yang diekstrak, IPv6 yang dihasilkan-DDoS Dataset di mana telah dikumpulkan oleh paket serangan yang dilakukan boleh ditukar kepada aliran rangkaian yang mengandungi metadata kaya tentang statistik setiap aliran, yang terdiri daripada data paket yang ditangkap. Aliran ini distruktur dalam bentuk data tabulus dan mengandungi ciri yang berterusan dan berbentuk kategori. Kemudian dikerahkan dalam teknik pembelajaran mendalam sebagai sistem pengesanan pencerobohan pada Dataset yang dibangunkan, lebih-lebih lagi dioptimumkan dalam pembelajaran hiperparameter (iaitu bilangan lapisan tersembunyi/neurons dan lain-lain) untuk mencari model pembelajaran mendalam yang optimum, dan memeriksa jika pengoptimuman lapisan/neuron akan menyumbang untuk meningkatkan ketepatan.

Oleh itu, hasil daripada teknik pembelajaran mendalam yang optimum bagi empat model yang dibangunkan Dataset DDoS-IPv6 adalah antara 99.79% dan 99.996% dan kerugian adalah di antara 0.0014% dan 0.781%. Kami mendapati bahawa semua teknik berjaya mengelaskan/mengesan serangan IPv6 dan ini akan membawa kepada penyelidikan lanjut baru perlu dibangunkan di kawasan ini.

INTRODUCTION

1.1 Introduction

In past years, there is a rapid rise globally on news about the distributed denial of service (DDoS) attack. Most private and/or government departments have become targets. A hacker group developed tools to execute DDoS attacks very easily and sell them to many people. As a result, DDoS attacks became one of the most harmful attacks in network security.

DDoS attacks are primarily to jam the services for a long time instead of taking money or data from the targets. Since a user might not re-use services jammed by crackers, a company attacked by the crackers will lose many benefits. A DDoS attack can be initiated from many computers hijacked by crackers, and then every computer will send large numbers of packets to the target server simultaneously. The server attempts to respond to all the packets, but its bandwidth gets exhausted very quickly and the service stops. A cracker who has hijacked many computers only sends some attack commands to the hijacked computers. These computers can be connected to multiple bots either directly or through a botnet. Consequently, detecting a cracker is extremely difficult. Hence, it seems that the right strategy is to detect DDoS attacks rather than crackers.

Intrusion detection systems are strategically placed on a network to detect threats and monitor packets. The intrusion detection system (IDS) accomplished this by collecting data from different systems and network sources, then analysing the data for possible threats [1]. The functions of the IDS include offering information on threats, taking corrective steps when it detects threats, and recording all important events within a network [2]. Different researchers have developed different classification representations [3-7], researchers have previously presented intrusion detection surveys and taxonomies [4, 8]. This research builds upon their work and

PT TAAUTHIM
PERPUSTAKAAN TUN KU TUN AMINAH

introduces deep learning networks techniques which are void of references. With the increasing value of big data, deep learning networks are an important element to capture a DDoS attack in an IDS. the taxonomy presented within this thesis provides a fine-grained overview of the different machine learning techniques for intrusion detection systems. The detection mainly depends on the source of data and intrusion technique used. The source of data is the nodes that gather the information for analysis.

Figure 1.1: DDoS Architecture [9]

Two typical methods are commonly used in IDS such as clustering and classification. It is difficult and costly to obtain the bulk of labelled network connection records for supervised training in the first stage. The clustering analysis has emerged as an anomaly intrusion detection approach in recent years [8]. Clustering is an unsupervised data exploratory technique that partitions a set of unlabelled data patterns into groups or clusters such that patterns within a cluster are similar to each other but dissimilar to another clusters' pattern. Meanwhile, classification is a supervised method to distinguish benign and malicious traffics on the basis of provided data which usually comes from clustering results as shown in Fig.1.2. The clustering and classification can be easily implemented by various machine learning methods.

Deep Learning is a branch of machine learning on the basis of a set of algorithms that attempt to model high-level data abstractions. Deep learning is also known as Neural Networks (NN) as it's inspired by the human brain's functionality to learn and identify objects e.g. vision. The human brain processes raw data which is

populated through our sensory inputs i.e. eyes and learns the features on its own by nature. Likewise, in deep learning, raw data is provided as input through the deep neural networks, which learns to identify the object and its features on which it is trained by algorithms. In Machine Learning, it requires manual inputs for selecting which features to process through the machine learning modules. Hence, the machine learning process is a bit slower and the result's accuracy may be affected by human errors. Deep learning's sophisticated, self-learning capability and intelligence results in higher accuracy and faster processing as compared to machine learning. Deep learning is also called deep machine learning, hierarchical learning, or deep structured learning. It can be unsupervised or supervised learning from the collected data on the basis of multiple layered models.

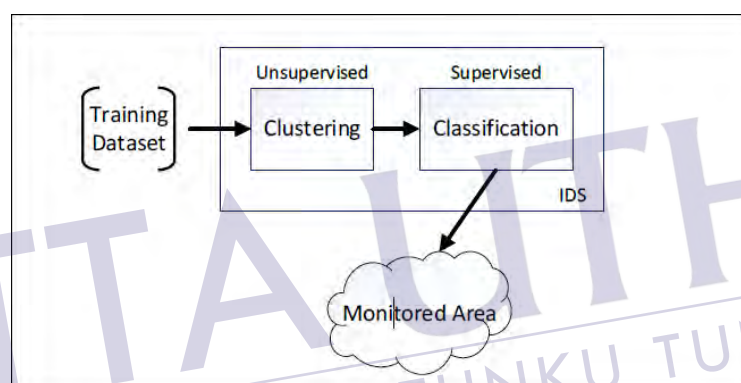

Figure 1.2: Common IDS approach [10]

there may be confusion about how to adopt deep learning in IDS applications properly since the different approaches have been adopted by previous work. Several types of research use deep learning methods in a partial sense only while the rest still uses conventional neural networks. The complexity of the deep learning method may be one of the reasons. Besides, the deep learning method requires a lot of time to train properly. Nonetheless, there are several researchers that adopted the deep learning method in their IDS research to compare the IDS performance among them. I claim that deep learning is very useful in IDS, especially for feature extraction. The feature extraction is a process of transforming raw data into features that are better represented for the underlying problem of the predictive models, resulting in improved model accuracy on unseen data. To support our claim, to provide future challenges and directions to employ deep learning in IDS accordingly. concluded that the deep learning method is suitable for pre-training or feature engineering/extraction, not as

the classifier. Finally, deep learning methods can enhance future research on unknown attack detection.

1.2 Problem Statement

The distributed nature of DDoS attacks tends to make it very difficult to defend against. The main aim of such an attack is to degrade networks, deplete network resources, and to prevent legitimate users from having access to network resources [11]. Furthermore, From the related works in section 2.4.1 and section 2.5.3 the major challenges have shown that facing researchers to develop the researches and challenges of the dataset such as (“no labelled DDoS attacks for IPv6, no data available online for download or use, few datasets on the internet but the security institutes or researchers who own it are kept private even for the research purposes).

Accordingly, accuracy analysis of Deep Learning techniques in IPv4 found that the accuracy rate that been reached between 60% to 99.92% as been explained in section 2.6. this raises a question that is, do deep learning will maintain similar/less or even better accuracy in DDoS IPv6 classification/detection?

Nevertheless, deep learning hyperparameters (i.e. number of hidden layers, number of neurons, etc.) would contribute to improving the accuracy. In other words, is there any positive/negative correlation between the accuracy/loss and other evaluation metrics when the architecture of the neural is changed? Another side question related to the types of deep learning deployed and the data pre-processing is yet to be figured out and/or discussed in the academic literature.

- Accuracy of Deep Learning techniques in IPv4 between 60% to 99.92%, this raises a question that is, does deep learning will maintain similar/less or even better accuracy in DDoS IPv6 classification/detection?
- Challenges of the dataset such as (“no labelled DDoS attacks for IPv6, no data available online for download or use, few datasets on the internet but the security institutes or researchers who own it are kept private even for the research purposes”).
- No available IPv6 dataset there would be no developed deep learning models for such type of dataset as shown in section 2.5.3. does deep learning will be a success as an intrusion detection system in IPv6

- Deep Learning Hyperparameters (i.e. the number of hidden layers, number of neurons etc.) would contribute to improving the accuracy. In other words, is there any positive/negative correlation between the accuracy/lose and other evaluation metrics when the architecture of the neural is changed?

1.3 Research Question

- What are the Deep Learning models that been used as Intrusion detection systems?
- What are the available datasets for DDoS attacks in IPv6?
- How to generate and collect DDoS IPv6 Dataset?
- What are the features of DDoS IPv6 attacks?
- What is the best deep learning model to classify DDoS ipv6 attacks?
- What is the optimal design for deep learning models on DDoS IPv6 classification attacks?
- How accurate the detection/classification of deep learning models on the developed dataset?

1.4 Objectives

The research objectives can be identified as follows

- To investigate the deep learning models as an intrusion detection system.
- To generate and collect dataset for anomaly DDoS flooding attack in real-time IPv6 environment. Then extract and prepare the features of the collected dataset towards creating a DDoS-IPv6 dataset.
- To develop deep learning models as based DDoS detection and classification models using developed dataset in objective (ii) on different deep learning models. Then optimize deep learning models' parameters (layers and neurons) using different model configurations towards identifying the optimal neural network design.
- To evaluate, compare, and validate the proposed DDoS flooding attacks detection technique identified in objective (iii) and (iv) using the available evaluation metrics.

1.5 Thesis Scope

- i. The most common DDoS attacks such as (Smurf, TCP-SYN, Router Advertisement Flooding Attack, and Various DDoS Attacks) on IPv6 have been used to develop our dataset.
- ii. The number of packets included was 1.2 million packets.
- iii. Used five personal computers.
- iv. Software used in our thesis, (python programming language, THC-IPv6, Ostinato, and Wireshark).
- v. The deep learning models utilized in this study are ANN, DNN, SAE, and CNN.
- vi. Used IPv6 environment due to the lack of research articles in this area (during the development of the literature, non-reviewed articles utilized deep learning models with DDoS IPv6).
- vii. The programming language used was a python, attacks system was Linux, the attacking tool was THC-IPv6 tool, and the monitoring software was Wireshark.

1.6 Research Outline

The layout of this research as Chapter two will include the systematic literature review with analysis and review principles been used in this research. Whereas Chapter three explains the methodological part been followed to fulfil the objective. In addition, Chapter four will present the method followed to generate and pre-process the IPv6 dataset. Chapter five will show the outcomes of our research. Lastly, Chapter six contains the discussion and future work of our research.

1.7 Summary

This chapter presents an introduction to our research and showing the problem statement, and objectives. Although it represents the research mapping and how the research conducted.

CHAPTER 2

LITERATURE REVIEW

2.1 Background

This chapter investigates the deep learning that been used as an intrusion detection system through a systematic literature review, then present a taxonomy in this area with an explanation for each class and subclasses. Moreover, discuss challenges, recommendations, and motivations in the related work. Additionally, a methodological aspect, critical analysis problem background and deep learning architecture are shown with an analysis for the latest related work in this field. Lastly, finalise the findings in section research gaps and present a summary for the chapter. The structure of the literature review and the purpose of each section is presented in the table below:

Table 2.1: Literature Review Sections and Their Purpose

SECTION	PURPOSE
2.2 Systematic review protocol	To choose the set of studies to review and analyse it. The protocol explains selection procedures such as inclusion, exclusion, resources, and the procedure of selection. Consequently, select the most relevant resources for our research.
2.3 Taxonomy	To identify the themes of selected studies towards selecting the path of our research and ease gaps identification.
2.4 Discussion	To identify the current challenges in the previously selected studies and the recommendations of the authors for future research. In addition to that the motivation behind their work. These elements can help to draw the shape of our problem statement and help to answer the question of why this research is important.

Table 2.1: Literature Review Sections and Their Purpose (Continued)

SECTION	PURPOSE
2.5 Methodological Aspect	To justify the configuration of our research. In addition to that the statistics configuration in the selected studies.
2.6 Critical Analysis	This section aims to narrow down the focus into a set of studies close to our research. Through the section, the result and the accuracy have been achieved in the selected studies.
2.7 Problem Background	four major challenges which are challenges related to DDoS attacks, Challenges of DDoS in IPv6, is the challenges faced by researchers in IPv6 Dataset, and lastly, challenges on IDS in IPv6
2.8 Deep Learning Layer With DDoS	To review the current researches done as an intrusion detection system on the basis of deep learning technique. In addition to that review under which network-layer DDoS attacks are classified and established.
2.9 Deep Learning Models	The section presents the architecture of deep learning models that been used in this research
2.10 Related Works Analysis Update	This section showing the latest related work with their analysis in this research field
2.11 Research Gaps	This section showing gaps and challenges in the related works that will be our objectives in this research
2.12 summary	This section summarises the findings of this chapter

2.2 Systematic Review Protocol

‘Deep learning’ DL is the most significant phrase in the scope of this study. Other artificial intelligence models that are not used as DL models are eliminated. For example, CNN, Deep Neural Network (DNN), and Autoencoder (AE) are used to develop intrusion detection systems (IDSs). I consider all areas related to intrusion detection and limit our scope to the English literature. Moreover, I use intruder and attacker as general categories.

2.2.1 Information sources

I proceed with the research on target articles and select the following digital databases:

(1) Web of Science (WoS) is an extensive database indexed as cross-disciplinary research. This database is selected to provide a comprehensive assessment of scientists' endeavours with an extensive view and to cover relevant technical literature.

(2) The ScienceDirect database provides an entry to journals and technical and science articles.

(3) The Xplore database of the Institute of Electrical and Electronics Engineers (IEEE) contains technical literature in electrical engineering, electronics, computer science, and other related fields.

(4) Scopus is the largest abstract database of peer-reviewed literature (i.e. scientific journals and conference proceedings).

2.2.2 Study selection

Study collection consists of two phases of scanning and filtering to search for literature resources. The first phase involves skimming titles and abstracts to exclude irrelevant articles and duplicates. The second phase involves reading the complete form of the selected manuscripts.

2.2.3 Search

This study started at the beginning of December 2017 through the advanced search boxes in the WoS, ScienceDirect, IEEE Xplore, and Scopus databases. I used a combination of diverse variations of keywords that consisted of 'deep learning,' 'intrusion' and 'attack' to perform our study. These keywords were combined with 'OR' and 'AND' operators. Figure 2.1 illustrates the exact query texts used in this study. I focused on two types of articles, namely, journal and conference articles, and used the preferences in each search engine to eliminate other types of reports and book chapters. In our survey on this emerging trend of intrusion detection, I assumed that the two areas consist of the latest and related scientific studies.

2.2.4 Eligibility criteria

Figure 2.1 lists the criteria that each article must satisfy. The initial goal was to plan the research on DL into an overall and coarse-grained taxonomy with three sets. I used Google Scholar and derived the categories from a pre-survey of related studies without limitations to obtain an initial perception of the background and directions of related papers. If the eligibility criteria were unsatisfied in the remaining articles after the initial removal of duplicates, then they were excluded from filtering and screening the articles. The exclusion criteria included having the objective of intrusion detection technology rather than non-DL models and not being written in English. A single Excel file with a complete list of all the articles from numerous resources with their equivalent initial categories was used to simplify the subsequent processing steps of data collection. I accomplished several full-text readings, and thus obtained a running classification of articles into a refined taxonomy and a large collection of highlights and comments on the surveyed studies. The major findings followed the processes of tabulation, description, and summarization. Excel and Word files were used to maintain a set of relevant information, including the source databases, their complete list of articles, description tables and summaries, categorization tables on the basis of attack type, review sources, objectives, number of features, and model used to develop DL, in addition to certain related information.

2.2.5 Results and statistical information of articles

The preliminary query resulted in 1,861 articles in the four databases: 1,203 in Scopus, 117 in IEEE Xplore, 477 in ScienceDirect, and 64 in WoS. This study grouped the filtered articles that were published from 2015 to 2018 into four categories. After scanning the titles and abstracts, the number of articles decreased to 179 from all the categories, and the duplicate articles were 59 out of 179. The final full-text reading and review excluded 52 papers. A total of 68 articles remained in the final set given the different topics related to DL as an intrusion detection technique.

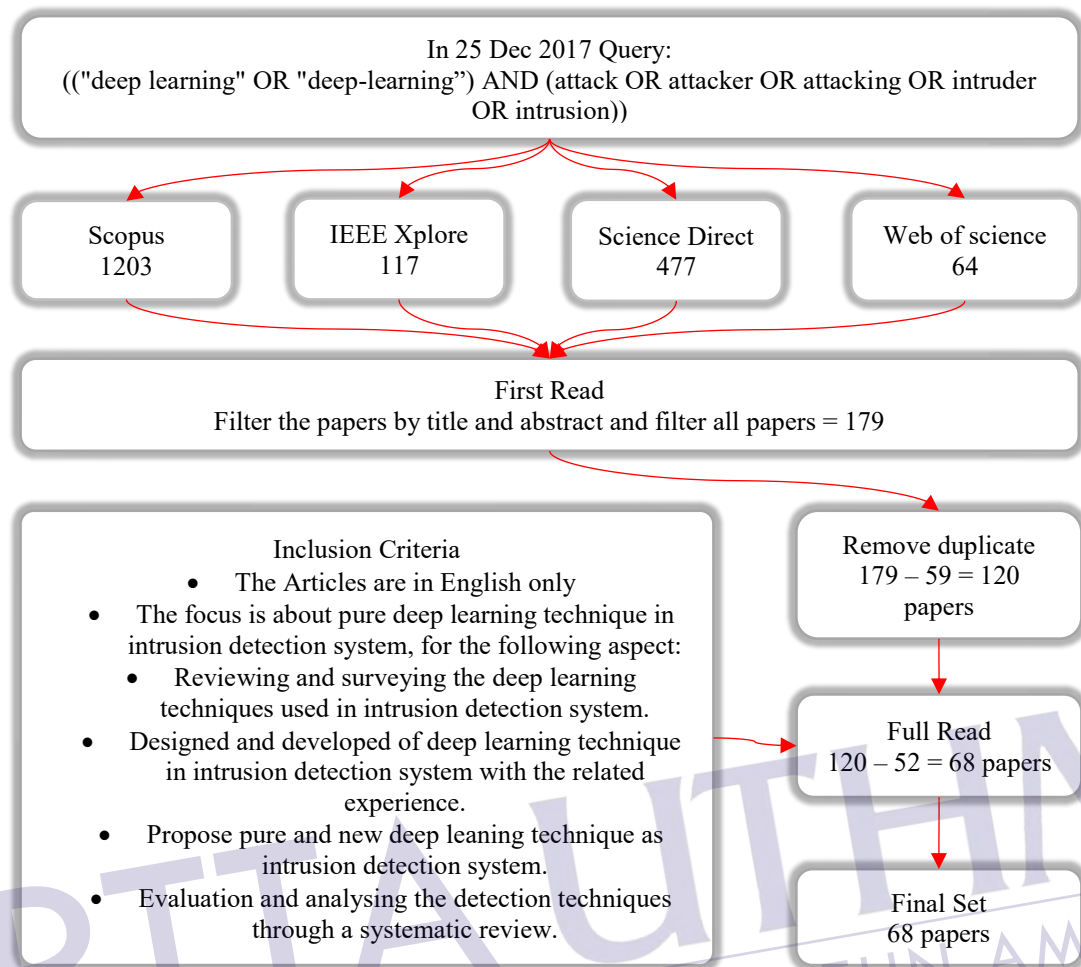

Figure 2.1: Flowchart Of Study Selection, Including The Search Query And Inclusion Criteria

2.3 Taxonomy

The classification suggests different classes and subclasses. Figure 2.2 illustrates the taxonomy of an IDS; it shows an inclusive improvement of several studies and applications. The first class includes articles associated with the objectives of this study. The second class includes articles on the number of techniques used as single or hybrid techniques to develop DL techniques to be used in IDSs. The third class comprises the artificial intelligence techniques used as DL techniques in IDSs. The largest proportion (72.06%; 49/68) relates to articles that develop an approach for evaluating or identifying intrusion detection techniques using the DL approach. The second-largest proportion (22.06%; 15/68) relates to studying/applying articles to the DL area, IDSs, or other related issues. The third-largest proportion (5.88%; 4/68) discusses frameworks/models for running or adopting IDSs. The taxonomy of the

literature presented in Figure 2.2 identifies several subcategories from the main classes.

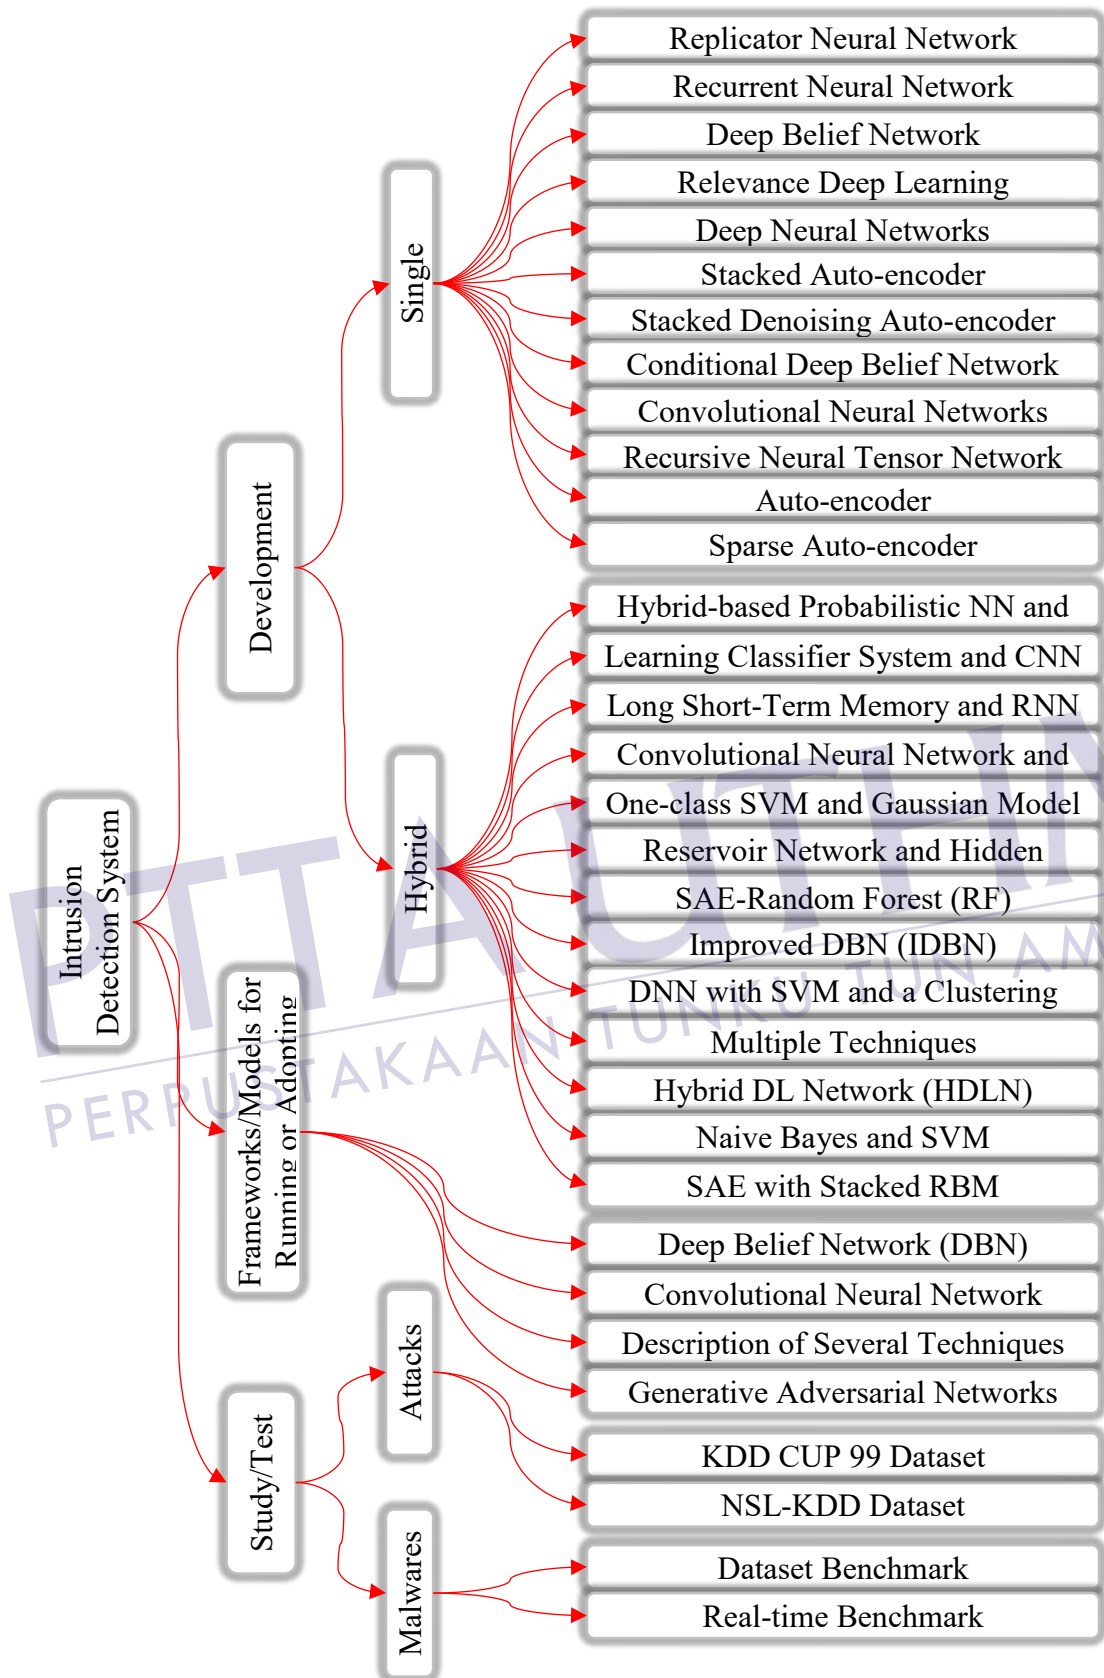

Figure 2.2: Taxonomy Of Literature On Intrusion Detection System On the basis of Deep Learning

2.3.1 Development

The first subsection in the classification of our taxonomy is divided into two sections, namely, single and hybrid techniques: -

2.3.1.1 Single Technique

This class is divided into 12 subclasses on the basis of the type of technique used to develop the DL technique.

A. Replicator Neural Networks

Replicator NNs, such as Autoencoders and NNs, are specific. These networks have been initially proposed as compression techniques that are trained to replicate the given input as an output. Compression can be achieved by using input units that are more than the units in the intermediate layer [12]. The principal component analysis (PCA) dimensionality reduction technique has confirmed that this compression process belongs to replicator NNs. An anomaly intrusion detection on the basis of DL that used replicator NNs was presented in [13]. Unsupervised dimensionality reduction was performed by the hidden layer between an encoder and a decoder. Therefore, the presented technique is on the basis of a decoder and an encoder, and this network corresponds to PCA. However, the proposed method did not exhibit accuracy when evaluated.

B. Recurrent neural network

This technique has a unique feature that is identical to a human brain process. That is, it can adopt the inner memory to process random sequences of inputs, and thus perform complex tasks, such as unsegmented and pattern recognition; moreover, this technique is ideal for handling real-time learning tasks given its capability to handle time-series data [14]. The following articles have adopted RNNs to build their DL technique.

Attack intrusion detection: An IDS on the basis of RNN was proposed in [15] by classifying the collected data. In the experiments, different hidden node numbers

and learning rate values were utilised for binary and multiclass classification. A realistic performance was accomplished by this technique, and computational processing was high. The authors of [16] developed a DL algorithm by using the preceding technique with Hessian-free optimisation to detect intrusions; the output exhibited relatively better performance in this technique than in the previous model. The false alarm rate was only 2.1%, and the detection rate was 95.37%. The authors of [17] suggested a system called DeepDefense, which adopts a DL-based distributed denial-of-service (DDoS) attack detection technique. The authors transformed packet-based DDoS detection to window-based detection and formulated DDoS detection as a series of classification problems to improve the performance in identifying DDoS attack traffic. The results confirmed that the models' performance depends on the dataset size, which does not depend on the system used for training.

Intruder behaviour detection: To predict the behaviour of users in Tor networks, the authors of [18] applied deep RNNs combined with kernel PCA and long short-term memory (LSTM)-RNN; their method consists of feature extraction, attack detection, and data pre-processing. Better performance than those of previous strategies was achieved by using this proposed threat analysis strategy. In another study, a framework was suggested to perform intruder detection and analysis using DL networks and association rule mining [14]. This framework can predict future intruder operations that may occur and the locations where these operations may be generated; then, it will show the progress of intruder attacks.

Malware detection: The authors of [19] proposed a natural language modelling that is similar to learning the language of malware spoken through the extraction of robust and executed instructions by using time-domain features. During the projection stage when features were extracted, the authors used RNNs to conduct experiments on malicious or benign files.

C. Deep Belief Network

A DBN is a Deep Neural Network model generated by a stacked Restricted Boltzmann machine (RBM), and the input of an RBM is the result of earlier RBMs, Between RBMs layers the information has become available on the system. Whole layers

provide a unidirectional connection, except for the two top layers, which provide a two-way connection. DBNs have been used as follows.

Android malware detection: A framework called ‘DeepSign’ was presented in [20] to detect malware automatically using a signature generation method on the basis of DBN. Registry entries, web searches, and port accesses formed the dataset on the basis of the behaviour logs of application programming interface (API) calls. The logs were converted into a binary vector in a sandbox. The result showed that using DBN for classification can achieve an accuracy of 98.6%. The authors of [21] proposed ‘DroidDeepLearner,’ an approach that uses a DL algorithm to address the current requirement for malware detection to become more autonomous at learning to solve problems with minimal human intervention for Android malware characterisation and identification. In their experiments, the DBN model performed better than various SVM models. The authors of [22] proposed ‘DroidDetector,’ an online DL-based Android malware detection engine that can detect whether an app is a malware or works automatically by using DL techniques to correlate the features from a static analysis with other features from dynamic analysis of the characterised malware and Android apps. Traditional (i.e. ML) techniques were outperformed, with a detection accuracy of 96.76%. The authors of [23] developed ‘DroidDelver,’ a programmed Android malware DS that utilises a DL structure that considers a DBN. From a small code extract, API call block features maintain an inherent relationship that exists within API calls.

Attack intrusion detection: An intelligent communication middleware was proposed to complement the conventional quality of service (QoS) evaluation that utilises the quality of experience (QoE) metrics in [24]. Communication infrastructure and data acquisition systems are crucial technologies for maintaining system economic reliability and efficiency. The proposed middleware effectively utilised traditional QoS criteria to detect and defend against potential congestion that attacks QoE evaluation from the operators of a power system. The authors of [25] used DBN to propose a NIDS for the security of in-vehicular networks. Detection accuracy was improved compared with those of earlier methods.

D. Relevance Deep Learning

The authors of [26] proposed a network intrusion detection technique on the basis of relevance DL, which learned a principle of deep relevance and the training algorithm of RBM. Relevance DL was applied to a NIDS to analyse the principle of feasibility in the NIDS. This technique was also applied to network intrusion detection technology and obtained high detection accuracy. The ratio of intrusion detection to normal data detection was 10:1. The average detection of a high-speed ultrahigh bandwidth network was greater than 50%, and the error rate was approximately 1.5%. These results indicated the effectiveness of the relevant DL algorithm in network intrusion detection.

E. Deep Neural Networks

DNNs, which provide powerful instruments to automatically produce high-level abstractions of complex multimodal data, have recently attracted considerable attention from industry and academia. DNNs learn features themselves, and thus the learning process becomes increasingly accurate; DNNs are verified to be more efficient and accurate than shallow learning [27]. The use of DNNs is presented as follows.

Attack intrusion detection: The authors of [27] proposed a high-level feature extraction capability of Internet of things systems that can be a resilient mechanism for novel attacks or small mutations. The compression capabilities and self-taught DL architecture are key mechanisms for hidden pattern discovery from the training data; hence, attacks are discriminated from benign traffic. The authors of [28] suggested a DNN with 3 hidden layers that use 41 features. The outcomes were mixed, i.e. those with more classes were less accurate than those that focused on fewer classes. The authors of [29] investigated the influence of fault injection attacks on DNNs. Through a fault injection attack by modifying the parameters used in DNNs, a specified input pattern was misclassified into an adversarial class that was attempted by attackers. The authors proposed two types of fault injection attacks to achieve these objectives. The first type was a single-bias attack that requires modifying only one parameter in the DNN for a misclassification on the basis of the observation outputs of the DNN that

may linearly depend on several parameters. The second type was a gradient descent attack that aims to reserve classification accuracy on input patterns other than the targeted one to force stealthy misclassification. Moreover, the manual burden placed on Department of Défense investigators was reduced by using the ML application in the early triage of security warnings that were reviewed as a case study in [30]. The triage tool prototype, called federated analysis security, was implemented in this study. Numerous daily events/alerts were summarized, categorized, and highlighted using the FAST prototype. The NN achieved a high classification accuracy of 98% and a log loss below 0.0001. Fivefold cross-validation obtained a result calculated from sample data.

Malware detection: A new adversary-resistant technique that prevents attackers from constructing influential adversarial samples by randomly nullifying features within data vectors was proposed in [31]; the accuracy of this technique was 73.59% in the Canadian Institute for Advanced Research (CIFAR) dataset and 98.43% in the Modified National Institute of Standards and Technology (MNIST) dataset. A malware detector that uses static features was proposed in [32] to deploy DNNs. The accuracy results of any previously published detection engine that used exclusively static features were less than those of this proposed approach. However, in the case of obfuscated binaries, static analysis may not provide satisfactory input for classification, and the authors did not consider dynamic analysis results in their research.

Spam detection: The authors of [33] proposed a novel technique on the basis of DL techniques. This technique constructed a binary classifier on the basis of the preceding representation dataset for the syntax of each tweet that will be learned through the Word Vector training phase. Performance evaluation was conducted from a 10-day ground-truth dataset with more than 600 million real-world tweets after the technique collected a part of the labelled data (376,206 spam and 73,836 no spam tweets). The data were pre-processed and converted into high-dimensional vectors by utilising the Word Vector technique.

F. Stacked Auto-encoder

Autoencoder layers and a logistic regression layer were used to construct SAE. SAE was built by stacking additional unsupervised feature learning layers through greedy methods for each additional layer and could be trained. I trained the new hidden layer by training a standard supervised NN with one hidden layer. SAE was used as follows.

Attack intrusion detection: A three-layer Wi-Fi impersonation attack detection system was developed in [34]. In the original dataset, SAEs firstly performed feature extraction through SAE and then feature selection through SVM, decision tree (DT), or artificial NN (ANN) on the newly extracted features and the original data. An ANN was used for the final classification. The proposed system results presented a 0.012% false-positive rate and a 99.918% detection rate. The deep features of an application-layer DDoS attack on the basis of a DL architecture that consisted of more than three layers were proposed in [35]. The concept of an Autoencoder was applied to the proposed work. The DL architecture aimed to receive high-level features using SAE. The proposed architecture achieved an average false positive rate of 1.27% and an average detection rate of 98.99%. The authors of [36] proposed various denial-of-service (DoS) attacks with timely detection against a computer or a network system on the basis of SAE. Their research focused on detecting application-layer DoS attacks by applying an anomaly detection-based approach to statistics extracted from network packets to utilize encrypted protocols. A classification scheme using a DL approach and a solution on the basis of anomaly detection was presented in [37]. The capability to perform attack classification accurately and the features necessary to detect network anomalies were self-learned in the DL approach. The overall accuracy of 98.6% was achieved through the SAE architecture frameworks formed on two and three hidden layers. The proposed frameworks can detect multipliable attacks in an IEEE 802.11 network. This network has high overall accuracy, considers novel attacks, and can perform four-class classification. A leveraged SAE was proposed in [38] to improve impersonation detection and classification by using weighted feature learning from shallow machine learners.

Android malware detection: The authors of [39] used a Linux-kernel system, called a graph-based DL framework, to propose an Android malware detection system on the basis of DL architecture with the SAE model. A DeepMalDroid method was

developed for dynamic analysis, rather than depending on a random event generator or user interactions.

G. Stacked Denoising Autoencoder

SDA, which is a development of traditional SAEs, introduces the structure and relevant terminology of a denoising Autoencoder [40]. A session-based network intrusion detection model using DL architecture was proposed in [31]. Researchers obtained relatively impressive results by applying an SDA-based DL architecture to detect botnet traffic.

H. Conditional Deep Belief Networks

CDBNs are extended versions of DBNs and have been presented to model temporal data by treating previously observed data through the implementation of an autoregressive data-modelling scheme and additional input to model temporal data. Real-time measurement data from geographically distributed phasor measurement units (PMUs) leverage physical coherence in power systems and are analysed using CDBNs to stabilise performance, probe and detect a data corruption scheme, verify the validity of lead agents' PMU data and estimate their true values [41]. The authors of [42] proposed a real-time detection technique. DL techniques on the basis of CDBN used historical measurement data and revealed features to detect false data injection (FDI) attacks in real-time and recognise the behaviour patterns of FDI attacks.

I. Convolutional Neural Network

The CNN process is similar to that of traditional ANNs, i.e. it consists of self-optimisation through learning neurons. Each neuron will operate and receive an input, such as a nonlinear function as a basis for countless ANNs [43]. CNNs are used as follows.

Hardware cybersecurity detection: This scheme was proposed as a CNN technique for securing the automated teller machines (ATMs) of banks because customers are prohibited from wearing a helmet whilst using ATMs. Google's

inception model was used for this purpose. The use of ATM surveillance camera feed can help improve security significantly as a form of automated helmet detection. The model achieved an accuracy of 95.3% whilst training on a proprietary ATM surveillance dataset [44].

Attack intrusion detection: The authors of [42] proposed a CNN that automatically learns the features of a graphic NSL-KDD dataset transformation by using a graphic conversion technique as an image conversion method for the dataset. The proposed technique is performed effectively and can be used as an anomaly detection classifier. A novel poisoning algorithm on the basis of the concept of back-gradient optimisation, i.e. to compute the gradient of interest through automatic differentiation, was proposed by the authors of [45] to extend the definition of poisoning attacks to multiclass problems and significantly reduce attack complexity whilst reversing the learning procedure. Their approach can target a wide class of learning algorithms compared with current poisoning strategies, including NN and CNN architectures that are trained with gradient-based procedures.

Android malware detection: The proposed CNN operation conducts classification along the sequence. The convolution window slides down the sequence to learn sequential patterns for each location and construct high-level features from small local features. CNN architecture uses multiple CNN layers. CNN is a natural choice for sequential data because its performance is considerably better than that of LSTM [46].

J. Recursive Neural Tensor Network

An RNTN, which is a development of RNN, is a tree-structured network similar to RNN that uses a tensor to improve its performance. A tensor is used to calculate a high-order composition of input features in RNTN after being enabled. On the basis of network behaviour, a technique was proposed in [47] to determine whether a dynamic analysis must be suspended to intensely and efficiently collect malware communication. Two characteristics of malware communication were focused on using the proposed technique, namely, the common latent function and the change in communication purpose. Overall, the proposed method reduced analysis time by 67.1% and avoided a complete analysis of 80.2% of the malware samples.

K. Auto-Encoder

Autoencoders aims to transform input into output with the least possible amount of distortion; they are considered a plain learning technique. Although they are theoretically simple, Autoencoders play an important role in ML. A three-stage algorithm was proposed in [48]. The first stage was a standardised dataset. The second stage produced a regression function by using DL depending on an Autoencoder model. The third stage produced a classifier function using a memetic. The system successfully classified 90.72% of the records. The authors of [49] proposed an Autoencoder technique for the real-time detection of cyber-physical attacks on water distribution systems. A test dataset that features several classes of plausible attacks was used to evaluate detection performance. The authors of [50] presented a new approach to network intrusion detection and classification for cybersecurity on an energy-efficient neuromorphic hardware platform by using DL algorithms on the basis of an Autoencoder. This Autoencoder was evaluated on IBM's True North Neurosynaptic CPU with less than 50 mow computation energy. The results achieved a classification rate of approximately 81.31% and an accuracy of nearly 90.12% for intrusion detection.

L. Sparse Auto-Encoder

The authors of [51] proposed a DL approach that depends on a sparse Autoencoder to implement a flexible and effective NIDS. A feature-learning task was realised completely unsupervised by using a Sparse Autoencoder. The result achieved a classification accuracy rate of over 98%.

2.3.1.2 Hybrid Technique

This class is divided into 13 subclasses on the basis of the type of hybrid techniques used to develop the following DL techniques.

A. Hybrid-based Probabilistic NN (PNN) and Deep Belief Network (DBN)

An intrusion detection strategy that utilises DBN and a probabilistic neural system was provided in [52]. Firstly, the major attributes of raw data were maintained to convert them into low-dimensional data through the nonlinear learning capability of DBN. Secondly, the number of hidden-layer nodes for each layer was increased by using a swarm optimisation algorithm to obtain optimal learning performance which reached 99.31%. Lastly, researchers of low-dimensional data who used PNN were categorised.

B. Learning Classifier System (LCS) and Convolutional Neural Network (CNN)

The authors of [53] proposed the convolutional neural-LCS (CN-LCS), which is a hybrid system that uses LCS and CNN for an IDS. CN-LCS can classify high-dimensional and sparse feature vectors of queries from data by using the automatic feature selection capability of convolution–pooling processes and a genetic algorithm. The model result achieved 94.64% accuracy.

C. Long Short-Term Memory (LSTM) and Recurrent Neural Network (RNN)

One work proposed a classifier for IDSs following the DL approach. Among six optimisations for the LSTM RNN model used as IDS, Nadam's optimiser was suitable for the LSTM RNN model in detecting intrusions. This classifier achieved a detection rate of 98.95% and a false alarm rate of 9.98%; these results indicated that this classifier demonstrated better performance than the other classifiers [54]. Another IDS model with the DL approach was on the basis of the LSTM architecture with RNN. This model achieved an attack detection percentage of 98.8%, an average false alarm rate of 10.03%, and normal instances of 10% [55].

PERPUSTAKAAN TUNJUNGU TUN AMINAH

D. Convolutional Neural Network (CNNs) and Stacked Autoencoders (SAEs)

A novel network intrusion model with the DL approach on the basis of stacked dilated convolutional Autoencoders was proposed in [56]. This method was evaluated on two new intrusion detection datasets. This network intrusion detection model merged the advantages of SAEs and CNNs. It can automatically learn additional unlabelled raw network traffic data that contain real-world traffic from botnets and important features from large-scale data, such as advanced persistent threats (APTs), normal traffic, scans, web-based malware, and exploits. The binary classification result achieved an accuracy rate between 97.91% and 98.62%.

E. One-class SVM (OC-SVM) and Gaussian Mixture Model (GMM)

This framework was built on the basis of two models to form a clustering model that can discover new anomalies [56]. The architecture obtained the capability to detect new anomalies. Multi-cluster anomalies were sorted using word2vec and subspace spectral ensemble clustering. These anomalies will be ignored by most unsupervised anomaly detection methods. The authors used weblogs to extract features manually and perform unsupervised anomaly detection by applying the features extracted by GMM and OC-SVM. The model outcome achieved approximately 0.8691 Rn and 0.8321 NMI. The model was 28 times faster than other techniques. The results validated that their model can cluster anomalies into correct categories.

F. Reservoir Network and Hidden Markov Model

Automatic identification is a type of integrity attack that affects cyber-physical systems; an innovative framework called 'IDAS' was proposed to address this issue [57]. The technique's architecture is on the basis of two models, namely, the reservoir network and the hidden Markov model, for a specific application scenario. The pattern recognition algorithms of different modelling properties were customised to learn their distribution, and a feature set was designed in the spectrum by capturing the characteristics of each attack. With regard to handling hidden attacks, a novel detection element was integrated. In terms of the future usage of the structure and
